Video

- Always pick the first element as a pivot.
- Always pick the last element as a pivot (implemented below)
- Pick a random element as a pivot.
- Pick median as the pivot.

```

graph TD
    A["{10, 80, 30, 90, 40, 50, 70}"] -- "Partition around 70 (Last element)" --> B["{10, 30, 40, 50}"]
    A -- "Partition around 70 (Last element)" --> C["{90, 80}"]
    B -- "Partition around 50" --> D["{10, 30, 40}"]
    B -- "Partition around 50" --> E["{}"]
    D -- "Partition around 40" --> F["{10, 30}"]
    D -- "Partition around 40" --> G["{}"]
    F -- "Partition around 30" --> H["{}"]
    F -- "Partition around 30" --> I["{}"]
    C -- "Partition around 80" --> J["{}"]
    C -- "Partition around 80" --> K["{90}"]
  
```

Counter variables

I: Index of smaller element

J: Loop variable

We start the loop with initial values

Test Condition	Actions	Value of variables
arr [J] <= pivot		I = -1 J = 0

- *Traverse elements from j = low to high-1*
 - **j = 0**: Since arr[j] <= pivot, do i++ and swap(arr[i], arr[j])
 - **i = 0**
- *arr[] = {10, 80, 30, 90, 40, 50, 70} // No change as i and j are same*
- **j = 1**: Since arr[j] > pivot, do nothing

Partition

Counter variables

I: Index of smaller element

J: Loop variable

Pass 2

Test Condition	Actions	Value of variables
arr [J] <= pivot		I = 0 J = 1
80 < 70 false	No Action	

- **j = 2**: Since arr[j] <= pivot, do i++ and swap(arr[i], arr[j])
- **i = 1**
- *arr[] = {10, 30, 80, 90, 40, 50, 70} // We swap 80 and 30*

Counter variables

I: Index of smaller element
J: Loop variable

Before Pass 7, J becomes 6
so we come out of the loop

Test Condition	Actions	Value of variables
arr [J] <= pivot		I = 3 J = 6

- We come out of loop because j is now equal to high-1.
- **Finally we place pivot at correct position by swapping arr[i+1] and arr[high] (or pivot)**
- `arr[] = {10, 30, 40, 50, 70, 90, 80}` // 80 and 70 Swapped

Partition

Counter Variable

I : Index of smaller element
J : Loop variable

We know swap arr[i+1] and pivot

I = 3

- Now 70 is at its correct place. All elements smaller than 70 are before it and all elements greater than 70 are after it.
- Since quick sort is a recursive function, we call the partition function again at left and right partitions

Start Your Coding Journey Now!

Since quick sort is a recursion function, we call the Partition function again

First 50 is the pivot.

As it is already at its correct position we call the quicksort function again on the left part.

- Again call function at right part and swap 80 and 90

Quick sort Right

80 is the Pivot

80 and 90 are swapped to bring pivot to correct position

Output

Sorted array:
1 5 7 8 9 10

Hoare's vs Lomuto Partition

Please note that the above implementation is Lomuto Partition. A more optimized implementation of QuickSort is Hoare's partition which is more efficient than Lomuto's partition scheme because it does three times less swaps on average.

How to pick any element as pivot?

We use cookies to ensure you have the best browsing experience on our website. By using our site, you acknowledge that you have read and understood our [Cookie Policy](#) & [Privacy Policy](#).

Start Your Coding Journey Now!

Analysis of QuickSort

Time taken by QuickSort, in general, can be written as follows.

$$T(n) = T(k) + T(n-k-1) + \theta(n)$$

The first two terms are for two recursive calls, the last term is for the partition process. k is the number of elements that are smaller than the pivot.

The time taken by QuickSort depends upon the input array and partition strategy. Following are three cases.

Worst Case:

The worst case occurs when the partition process always picks the greatest or smallest element as the pivot. If we consider the above partition strategy where the last element is always picked as a pivot, the worst case would occur when the array is already sorted in increasing or decreasing order. Following is recurrence for the worst case.

$$T(n) = T(0) + T(n-1) + \theta(n) \text{ which is equivalent to } T(n) = T(n-1) + \theta(n)$$

The solution to the above recurrence is (n^2) .

Best Case:

The best case occurs when the partition process always picks the middle element as the pivot. The following is recurrence for the best case.

$$T(n) = 2T(n/2) + \theta(n)$$

We use cookies to ensure you have the best browsing experience on our website. By using our site, you acknowledge that you have read and understood our [Cookie Policy](#) & [Privacy Policy](#).

Start Your Coding Journey Now!

and calculate time taken by every permutation which doesn't look easy.

We can get an idea of average case by considering the case when partition puts $O(n/9)$ elements in one set and $O(9n/10)$ elements in other set. Following is recurrence for this case.

$$T(n) = T(n/9) + T(9n/10) + \theta(n)$$

The solution of above recurrence is also $O(n \log n)$:

Although the worst case time complexity of QuickSort is $O(n^2)$ which is more than many other sorting algorithms like [Merge Sort](#) and [Heap Sort](#), QuickSort is faster in practice, because its inner loop can be efficiently implemented on most architectures, and in most real-world data. QuickSort can be implemented in different ways by changing the choice of pivot, so that the worst case rarely occurs for a given type of data. However, merge sort is generally considered better when data is huge and stored in external storage.

Is QuickSort **stable**?

The default implementation is not stable. However any sorting algorithm can be made stable by considering indexes as comparison parameter.

Is QuickSort **In-place**?

As per the broad definition of in-place algorithm it qualifies as an in-place sorting algorithm as it uses extra space only for storing recursive function calls but not for manipulating the input.

What is 3-Way QuickSort?

We use cookies to ensure you have the best browsing experience on our website. By using our site, you acknowledge that you have read and understood our [Cookie Policy](#) & [Privacy Policy](#).

Start Your Coding Journey Now!

`arr[l..r]` is divided in 3 parts:

- `arr[l..i]` elements less than pivot.
- `arr[i+1..j-1]` elements equal to pivot.
- `arr[j..r]` elements greater than pivot.

See [this](#) for implementation.

How to implement QuickSort for Linked Lists?

[QuickSort on Singly Linked List](#)

[QuickSort on Doubly Linked List](#)

Can we implement QuickSort Iteratively?

Yes, please refer [Iterative Quick Sort](#).

Why Quick Sort is preferred over MergeSort for sorting Arrays ?

Quick Sort in its general form is an in-place sort (i.e. it doesn't require any extra storage) whereas merge sort requires $O(N)$ extra storage, N denoting the array size which may be quite expensive. Allocating and de-allocating the extra space used for merge sort increases the running time of the algorithm. Comparing average complexity we find that both type of sorts have $O(N\log N)$ average complexity but the constants differ. For arrays, merge sort loses due to the use of extra $O(N)$ storage space.

Most practical implementations of Quick Sort use randomized version. The randomized version has expected time complexity of $O(n\log n)$. The worst case is possible in randomized version also, but worst case doesn't occur for a particular pattern (like sorted array) and randomized Quick Sort works well in practice. Quick Sort is also a cache friendly sorting algorithm as it has good locality of reference when used for arrays.

Quick Sort is also tail recursive. therefore tail call optimizations is done.

We use cookies to ensure you have the best browsing experience on our website. By using our site, you acknowledge that you have read and understood our [Cookie Policy](#) & [Privacy Policy](#).

Start Your Coding Journey Now!

adjacent in memory. Unlike array, in linked list, we can insert items in the middle in $O(1)$ extra space and $O(1)$ time. Therefore merge operation of merge sort can be implemented without extra space for linked lists.

In arrays, we can do random access as elements are continuous in memory. Let us say we have an integer (4-byte) array A and let the address of A[0] be x then to access A[i], we can directly access the memory at $(x + i * 4)$. Unlike arrays, we can not do random access in linked list. Quick Sort requires a lot of this kind of access. In linked list to access i'th index, we have to travel each and every node from the head to i'th node as we don't have continuous block of memory. Therefore, the overhead increases for quick sort. Merge sort accesses data sequentially and the need of random access is low.

How to optimize QuickSort so that it takes $O(\log n)$ extra space in worst case?

Please see [QuickSort Tail Call Optimization \(Reducing worst case space to \$\log n\$ \)](#)

- [Quiz on QuickSort](#)
- [Recent Articles on QuickSort](#)
- [Coding practice for sorting.](#)

Advantages of Quick Sort:

- It is a divide-and-conquer algorithm that makes it easier to solve problems.
- It is efficient on large data sets.
- It is a stable sort, meaning that if two elements have the same key, their relative order will be preserved in the sorted output.
- It has a low overhead, as it only requires a small amount of memory to function.

Disadvantages of Quick Sort:

- It has a worst-case time complexity of $O(n^2)$, which occurs when the pivot is

We use cookies to ensure you have the best browsing experience on our website. By using our site, you acknowledge that you have read and understood our [Cookie Policy](#) & [Privacy Policy](#).

Start Your Coding Journey Now!

Summary:

- Quick sort is a fast and efficient sorting algorithm with an average time complexity of $O(n \log n)$.
- It is a divide-and-conquer algorithm that breaks down the original problem into smaller subproblems that are easier to solve.
- It can be easily implemented in both iterative and recursive forms and it is efficient on large data sets, and can be used to sort data in-place.
- However, it also has some drawbacks such as worst case time complexity of $O(n^2)$ which occurs when the pivot is chosen poorly.
- It is not a good choice for small data sets, it is not cache-efficient, and is sensitive to the choice of pivot.
